Post-quantum public key algorithms for the Secure Shell (SSH) protocol
draft-kampanakis-curdle-pq-ssh

Abstract

This document defines hybrid key exchange methods based on classical ECDH key exchange and post-quantum key encapsulation schemes. These methods are defined for use in the SSH Transport Layer Protocol. It also defines post-quantum public key authentication methods based on post-quantum signature schemes. These methods are defined for use in the SSH Authentication Protocol.

EDNOTE: The goal of this draft is to start the standardization of PQ algorithms in SSH early to mitigate the potential record-and-harvest later with a quantum computer attacks. This draft is not expected to be standardized before the NIST PQ Project has standardized PQ algorithms. After NIST has standardized then this document will replace TBD1, TBD2, TBD3 with the appropriate algorithms and parameters before proceeding to standardization.

EDNOTE: Discussion of this work is encouraged to happen on the IETF WG Mailing List or in the GitHub repository which contains the draft: <https://github.com/csosto-pk/pq-ssh/issues> .

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on 12 April 2021.

1. Introduction

Secure Shell (SSH) [RFC4251] performs key establishment using key exchange methods based exclusively on (Elliptic Curve) Diffie-Hellman style schemes. SSH [RFC4252], [RFC8332], [RFC5656], [RFC8709] also define public key authentication methods based on RSA or ECDSA/EdDSA signatures schemes. The cryptographic security of these key exchange and signature schemes relies on certain instances of the discrete logarithm and integer factorization problem being computationally infeasible to solve for adversaries.

However, when sufficiently large quantum computers becomes available these instances would no longer be computationally infeasible rendering the current key exchange and authentication methods in SSH insecure [I-D.hoffman-c2pq]. While large quantum computers are not available today an adversary can record the encrypted communication sent between the client and server in an SSH session and then later decrypt the communication when sufficiently large quantum computers become available. This kind of attack is known as a "record-and-harvest" attack. "Record-and-harvest" attacks do not apply retroactively to authentication but a quantum computer could threaten SSH authentication by impersonating as a legitimate client or server.

This document proposes to address the problem by extending the SSH Transport Layer Protocol [RFC4253] with hybrid key exchange methods and the SSH Authentication Protocol [RFC4252] with public key methods based on post-quantum signature schemes. A hybrid key exchange method maintains the same level of security provided by current key exchange methods, but also adds quantum resistance. The security provided by the individual key exchange scheme in a hybrid key exchange method is independent. This means that the hybrid key exchange method will always be at least as secure as the most secure key exchange scheme executed as part of the hybrid key exchange method.

In the context of the NIST Post-Quantum Cryptography Standardization Project [NIST_PQ], key exchange algorithms are formulated as key encapsulation mechanisms (KEMs), which consist of three algorithms:

- * 'KeyGen() -> (pk, sk)': A probabilistic key generation algorithm, which generates a public key 'pk' and a secret key 'sk'.
- * 'Encaps(pk) -> (ct, ss)': A probabilistic encapsulation algorithm, which takes as input a public key 'pk' and outputs a ciphertext 'ct' and shared secret 'ss'.

- * `'Decaps(sk, ct) -> ss'`: A decapsulation algorithm, which takes as input a secret key `'sk'` and ciphertext `'ct'` and outputs a shared secret `'ss'`, or in some cases a distinguished error value.

The main security property for KEMs is indistinguishability under adaptive chosen ciphertext attack (IND-CCA2), which means that shared secret values should be indistinguishable from random strings even given the ability to have arbitrary ciphertexts decapsulated. IND-CCA2 corresponds to security against an active attacker, and the public key / secret key pair can be treated as a long-term key or reused. A weaker security notion is indistinguishability under chosen plaintext attack (IND-CPA), which means that the shared secret values should be indistinguishable from random strings given a copy of the public key. IND-CPA roughly corresponds to security against a passive attacker, and sometimes corresponds to one-time key exchange.

The corresponding post-quantum signature algorithms defined in the NIST Post-Quantum Cryptography Standardization Project [NIST_PQ] are

- * `'KeyGen() -> (pk, sk)'`: A probabilistic key generation algorithm, which generates a public key `'pk'` and a secret key `'sk'`.
- * `'Sign(m, sk) -> sig'`: A deterministic signing algorithm, which takes as input a message `'m'` and a private key `'sk'` and outputs a signature `'sig'`.
- * `'Verify(m, pk, sigma) -> pass/fail'`: A verification algorithm, which takes as input a message `'m'`, a public key `'pk'` and a signature `'sig'` and outputs a verification pass or failure of the signature on the message.

The post-quantum KEMs used for hybrid key exchange in the document are TBD1, TBD2. The post-quantum signature algorithm used for key based authentication is TBD3. [EDNOTE: Placeholder. Algorithms will be identified after NIST Round 3 concludes.] The post-quantum algorithms are defined in NIST Post-quantum Project [NIST_PQ].[EDNOTE: Update link. Algorithms can change based on NIST's Round 3 standardization].

1.1. Requirements Language

The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described in RFC 2119 [RFC2119].

2. Hybrid Key Exchange

2.1. Hybrid Key Exchange Method Abstraction

This section defines the abstract structure of a hybrid key exchange method. The structure must be instantiated with two key exchange schemes. The byte, string and mpint are to be interpreted in this document as described in [RFC4251].

The client sends

```
byte SSH_MSG_HBR_INIT
string C_INIT
```

Where C_INIT would be the concatenation of C_PQ and C_CL.

The server sends

```
byte SSH_MSG_HBR_REPLY
string S_REPLY
```

Where S_REPLY would be the concatenation of S_PQ and S_CL.

C_PQ represents the 'pk' output of the corresponding KEMs' 'KeyGen' at the client. S_PQ represents the ciphertext 'ct' output of the corresponding KEMs' 'Encaps' algorithm generated by the server to the client's public key. The client decapsulate ct using its private key which leads to K_PQ, a post-quantum shared secret for SSH.

C_CL and S_CL represent the ephemeral public key of the client and server respectively used for the classical (EC)DH key exchange which leads to K_CL, a classical shared secret for SSH.

XXX For Curve25519 the C_CL is represented as a fixed length 32 byte string, for example. XXX

2.2. Key Derivation

The shared secrets K_CL and K_PQ are the output from the two key exchange schemes X and Y, respectively, that instantiates an abstract hybrid key exchange method Section 2. The SSH shared secret K is derived as the hash algorithm specified in the named hybrid key exchange method name over the concatenation of K_PQ and K_CL:

$$K = \text{HASH}(K_{\text{PQ}}, K_{\text{CL}})$$

The resulting bytes are fed as to the key exchange method's hash function to generate encryption keys.

2.3. HASH

Derivation of encryption keys MUST be done according to Section 7.2 in [RFC4253] with a modification on the exchange hash H. The hybrid key exchange hash H is the result of computing the HASH, where HASH is the hash algorithm specified in the named hybrid key exchange method name, over the concatenation of the following

```
string V_C, client identification string (CR and LF excluded)
string V_S, server identification string (CR and LF excluded)
string I_C, payload of the client's SSH_MSG_KEXINIT
string I_S, payload of the server's SSH_MSG_KEXINIT
string C_INIT, client message octet string
string S_REPLY, server message octet string
string K, SSH shared secret
```

The HASH function used for the definitions in this specification are SHA-256 [nist-sha2] [RFC4634].

2.4. Hybrid Key Exchange Method Names

The hybrid key exchange method names defined in this document are

```
ecdh-nistp256-TBD1-sha256
x25519-TBD1-sha256
```

XXX Hybrid scheme currently implemented: sntrup4591761x25519-sha512@tinyssh.org XXX

[EDNOTE: Placeholder. Algorithms will be identified after NIST Round 3 concludes.]

2.4.1. ecdh-nistp256-TBD1-sha256

ecdh-nistp256-TBD1-sha256 defines that the classical C_CL or S_CL from the client or server NIST P-256 curve public key as defined in [nist-sp800-186]. Private and public keys are generated as described therein. Public keys are defined as strings of 32 bytes for NIST P-256. The K_CL shared secret is generated from the exchanged C_CL and S_CL public keys as defined in [RFC5656] (key agreement method ecdh-sha2-nistp256) with SHA-256 [nist-sha2] [RFC4634] instead of SHA-256 as the hash.

The post-quantum C_PQ or S_PQ string from the client and server are TBD1. The K_PQ shared secret is decapsulated from the ciphertext S_PQ using the client private key [EDNOTE: Placeholder. Update based on the algorithm identified after NIST Round 3 concludes.]

2.4.2. x25519-TBD1-sha256

x25519-TBD1-sha256 defines that the classical C_CL or S_CL from the client or server is Curve25519 public key as defined in [RFC7748]. Private and public keys are generated as described therein. Public keys are defined as strings of 32 bytes for Curve25519. The K_CL shared secret is generated from the exchanged C_CL and S_CL public keys as defined in [RFC8731] (key agreement method curve25519-sha256) with SHA-256 [nist-sha2] [RFC4634] instead of SHA-256 as the hash.

The post-quantum C_PQ or S_PQ string from the client and server are TBD1. The K_PQ shared secret is decapsulated from the ciphertext S_PQ using the client private key as defined in [EDNOTE: Placeholder. Update based on the algorithm identified after NIST Round 3 concludes.]

3. Key Authentication

[EDNOTE: Discuss if hybrid auth keys which combine classical and PQ signatures are necessary. Since authentication cannot be broken retroactively, even if the PQ signature algorithms got broken, we could switch to a classical algorithm to at least keep the classical security. On the other hand, that would take time to deploy while these entities would be vulnerable to impersonation attacks. Hybrid signatures add some overhead, but could provide the peace of mind of remaining secure with the classical algorithm without scrambling to deploy a change even if the PQ algorithms got broken.]

3.1. Public Key Format

```
string    "ssh-TBD3"
string    key
```

Here, 'key' is the x-octet public key described in the TBD3 specification.

[EDNOTE: Placeholder. Algorithms will be identified after NIST Round 3 concludes.]

3.2. Signature Format

```
string    "ssh-TBD3"
string    signature
```

Here, 'signature' is the x-octet signature produced in accordance with the TBD3 specification.

[EDNOTE: Placeholder. Algorithms will be identified after NIST Round 3 concludes.]

3.3. Signing and Verification

Signatures are generated according to the procedure in TBD3 specification

Signatures are verified according to the procedure in TBD3 specification

[EDNOTE: Placeholder. Algorithms will be identified after NIST Round 3 concludes.]

4. Message Size

An implementation adhering to [RFC4253] must be able to support packets with an uncompressed payload length of 32768 bytes or less and a total packet size of 35000 bytes or less (including 'packet_length', 'padding_length', 'payload', 'random padding', and 'mac'). These numbers represent what must be 'minimally supported' by implementations. This can present a problem when using post-quantum key exchange schemes because some post-quantum schemes can produce much larger messages than what is normally produced by existing key exchange methods defined for SSH. This document does not define any named domain parameters (see Section 7) that cause any hybrid key exchange method related packets to exceed the minimally supported packet length. This document does not define behaviour in cases where a hybrid key exchange message cause a packet to exceed the minimally supported packet length.

5. Acknowledgements

6. IANA Considerations

This memo includes requests of IANA for SSH_MSG_HBR_INIT, SSH_MSG_HBR_REPLY, ecdh-nistp256-TBD1-sha256, x25519-TBD1-sha256, and ssh-TBD3.

7. Security Considerations

[EDNOTE: The security considerations given in [RFC5656] therefore also applies to the ECDH key exchange scheme defined in this document. Similarly for the X25519 document. PQ Algorithms are newer and standardized by NIST. And more. Should include something about the combination method for the KEM shared secrets.]

[EDNOTE: Discussion on whether an IND-CCA KEM is required or whether IND-CPA suffices.] Any KEM used in the manner described in this document MUST explicitly be designed to be secure in the event that the public key is re-used, such as achieving IND-CCA2 security or having a transform like the Fujisaki-Okamoto transform [FO][HHK] applied. While it is recommended that implementations avoid reuse of KEM public keys, implementations that do reuse KEM public keys MUST ensure that the number of reuses of a KEM public key abides by any bounds in the specification of the KEM or subsequent security analyses. Implementations MUST NOT reuse randomness in the generation of KEM ciphertexts.
